INVENTORY OF MARINE MOLLUSCS OF FRENCH POLYNESIA

BY

JEAN TRÖNDLÉ¹ AND MICHEL BOUTET²

ABSTRACT

An inventory of marine molluscan species from French Polynesia has been updated following recent field collections and numerous consultations of many shells collections. A total of 2373 species were analysed of which 1702 were identified: 13 chitons, 194 bivalves, 1 scaphopod, 8 cephalopods and 1486 gastropods. The present inventory indicates that the malacological fauna is more diverse than previously reported: 1008 species were identified by Dautzenberg and Bouge (1933) and 1061 species were identified by Richard (1975). A total of 671 species were not identified of which at least 21 are new to science and will be described in the near future.

RÉSUMÉ

L'inventaire des espèces de mollusques marins de Polynésie française est mis à jour au vu de collectes récentes et de l'examen de plusieurs collections. Au total 2373 espèces ont été séparées et comptabilisées dont 1702 ont été identifiées soit 13 chitons, 194 bivalves, 1 scaphopode, 8 céphalopodes et 1486 gastéropodes. Cet inventaire fait état d'une faune malacologique bien plus importante que celles des auteurs précédents: 1008 espèces pour Dautzenberg et Bouge (1933) et 1061 espèces identifiées pour Richard (1975). Un total de 671 espèces n'ont pu être identifiées dont 21 au moins d'entre elles sont actuellement considérées comme nouvelles pour la science et feront prochainement l'objet de publications.

INTRODUCTION

French Polynesia (Fig. 1) consisting of 118 volcanic and low coral reef islands in Oceania is oriented on a South East – North West axis between 8 and 28° South latitude and 134 and 155° West longitude. The exclusive economic zone is more than 5 millions km². Land area covers 3,726 km² and the coral reef ecosystem covers 15,047 km² (2,140 km² of reefs and 12,907 km² of lagoons). Geomorphological diversity is very important among all these islands (Salvat et al., 2008). The Society archipelago is a perfect illustration of islands emerging from hot spots which drift with the oceanic floor: the youngest are volcanic islands without reefs (e.g. Mehetia), then islands become surrounded by reefs (e.g. Tahiti, Moorea), then follows considerable subsidence of the volcanic substrate leaving a large lagoon (e.g. Bora Bora) and finally true atolls (e.g.

Scilly). The Tuamotu archipelago, consisting of 76 atolls (either open with passes, closed or elevated), is one of the richest groups of atolls in the world. The Marquesas archipelago lacks barrier reefs and lagoons and has a poor coral fauna. The Austral archipelago consists of either volcanic islands with lagoons (e.g. Raevavae) or islands without lagoons but with coral reef beds (e.g. Rapa). These two last archipelagos are known to have endemic marine species.

Since the 18th century, large expeditions have collected fauna and flora of French Polynesian islands including marine molluscs (see Tröndle and Van Cossel, 2005). The first inventory of marine molluscs of Oceania was by Dautzenberg and Bouge in the *Journal de Conchyliologie* (1933). The first author was a Belgian malacologist while the second, an enlightened amateur, was French Polynesia's Governor between 1928 and 1931. In 1975 "Coquillages de Polynésie" was edited by Salvat and Rives illustrating more than 400 species with colour photos. In 1985, for the fifth international coral reefs symposium in Tahiti, Richard published a list of 1159 species, 98 of which were unidentified. These inventories also gave the species distributions known at that time.

The present inventory takes into account only those species from past inventories whose presence has been confirmed by the present authors during field expeditions and from collections at the Muséum National d'Histoire Naturelle Paris (MNHN), at the Centre de Recherches Insulaires et Observatoire de l'Environnement de Moorea en Polynésie française (CRIOBE), at the Ecole Pratique des Hautes Etudes (EPHE - Université de Perpignan), at the National Museum of Natural History Washington D.C. (USNM) and from several local French Polynesian private collections.

Two recent expeditions to the Marquesas (1997) and Austral archipelago (2002) provided the most valuable inventories of marine molluscs and greatly enlarged our faunistical knowledge. The first one, organized by the MNHN in collaboration with the Institut de Recherches pour le Développement (IRD), "MUSORSTOM 9" expedition, collected fauna from 168 stations between 40 and 1250 m depth. An additional 40 stations were prospected in the littoral zone on Ua Huka. The second expedition, jointly organized by CRIOBE, IRD and MNHN, "BENTHAUS expedition", worked in Rapa at 159 dredge stations between 50 and 1800 m depth and with 99 additional stations in the littoral zone.

The present list of molluscs in French Polynesia is the first step of an inventory which will be completed with a future article that will provide information and argumentation on each species with their references.

The following abbreviations are used to mention the geographical distribution of the species :

S : Society Islands

T : Tuamotu Islands

G : Gambier Islands

M : Marquesas Islands

A : Austral Islands

m. add. : additional morphospecies recognized, but not identified

LIST OF SPECIES

The list of molluscs follows the systematic order adopted by Beesley et al. (1998), except for the Colubrariidae family which is itself considered as a family (Bouchet and Rocroi, 2005). All genera and species are listed in alphabetic order within each family. Sub-families, sub-genera and sub-species are not mentioned, except for the Coralliophilinae which is a special group that was considered distinct from the Muricidae for a long time.

CONCLUSIONS

Dautzenberg and Bouge (1933) listed **1008** species for French Polynesia, together with numerous varieties, some of which are now considered distinct species. On the other hand, some taxa which they listed are now considered either synonyms or their presence has not been confirmed by our study. It was not our objective to discuss synonymy in the present study. Richard (1985) listed **1159** species. Our study records **2373** species of which at least **21** are new. Part of the material collected during the Marquesas and Austral expeditions are still under review, including many small molluscs. We consider that the whole marine malacological fauna of French Polynesia consists of over 2500 species.

ACKNOWLEDGEMENTS

We thank Bernard Salvat who encouraged us to establish this list in the framework of a new inventory of reef species after the one established by Richard (1985) at CRIOBE-EPHE in Moorea (Directors René Galzin and Serge Planes). This up-dated list is also a reference for the barcoding project in French Polynesia headed by Neil Davies, Gustav Paulay and Serge Planes (University of Berkeley – Gump Research Station –, University of Florida, CRIOBE-EPHE, Moorea).

We are especially grateful to Philippe Bouchet and his team (Virginie Heros, Pierre Lozouet and Philippe Maestrati) in the National Museum of Natural History, Paris, for their advice and for greatly facilitating consultation of collections.

We thank all those who helped by allowing us to consult their collections and giving documents and information : C. Beslu (Mahina, Tahiti), A.G. Beu (GNS Science), R. Bieler (FMNH), M. Balleton (Tautira, Tahiti), D. Brabant (MNHN), W.O. Cernohorsky (AIM), R. von Cosel (MNHN), H.H. Dijkstra (Université d'Amsterdam), D.L Geiger (SBMNH), H. Guiot (Société des Océanistes, Paris), R. Thanks for the English translation go to Bernard Salvat and Suzanne Mills.

We would like to express our considerable thanks to Gustav Paulay for an attentive review of our paper along with many comments that we have taken into account.
